Abstract

This paper primarily aims at the presentation of experimental results or case studies conducted in a number of 3 or 5 poultry farms within the Bihor county, accommodating valuable genitors belonging to the LEGHORN breed.

Key words: Leghorn breed, body weight rating

INTRODUCTION

Poultry breeding represents a genuine source of knowledge and genetic resources for the advancement of poultry raising, both globally and nationally. In this context, the number of specialists concerned about this activity is increasingly reduced, on the first place being the socio-economic situation and current laws, poultry raising using superintensive systems, generating secure incomes providing the economic agents a certain possibility of development.

Unfortunately, there isn't a national program of conservation / improvement of the of valuable populations of domestic poultry, in this way being wasted the implicit benefits that can be generated through the exploitation of genetic resources of some breeds internationally recognized.

MATERIAL AND METHOD

The material used in biological experiments consisted of birds of both sexes, at different ages (hatching during the juvenile period, to attain sexual maturity during the active breeding) and belonging to the following taxonomic category of zoological class Aves:

- *Galliformes*:
 - *Gallus bankiva domesticus* species – hen, **Leghorn breed.**

To determine the weight, the gravimetric method was used, making individual weighing with analytical balance, made at hatching and weekly for young, male and female category.

The material used in biological experiments consisted of birds of both sexes, at different ages (hatching during the juvenile period, to attain sexual

maturity during the active breeding) and belonging to the following taxonomic category of zoological class Aves:

- *Galliformes*:
 - *Gallus bankiva domesticus* species – hen, **Leghorn breed.**

To determine the weight, the gravimetric method was used, making individual weighing with analytical balance, made at hatching and weekly for young, male and female category.

RESULTS AND DISCUSSION

Body weight at Leghorn breed, youth category (0-20 weeks) was rated at hatching and then every 7 days, by individual weighing up to the age of 20 weeks.

Some of the data were extracted from the record books of the 5 farms considered for the study.

Results on the dynamics of individual weight are presented in tables 1 and 2. and in figure 1.

For cockerels, taken in the overall study was 45 individuals, divided as follows: 10 heads - Farm 1, 8 heads. – farm 2, 12 heads - farm 3, 10 heads - Farm 4, 6 heads - Farm 5.

In the case of pullets, an actual of 131 birds has been reviewed, spread across the 5 farms considered for the study: 30 heads -farm1, 26 heads -farm 2, 40 heads - farm 3 and 20 heads - Farm 5.

Thus, it was found an average weight of 39.9 g at the one-day cockerels, between the value of 38.5 ± 0.3 g (C3) and 41.5 ± 0.8 g (C1). The lots had a good consistency, with a coefficient of variation situated around the value of 4%.

A similar situation was encountered in the case of pullets, the first day posthatching, they registering an average weight in the 5 farms of 39.4 g, contained in the range of 38.2 ± 0.4 g and $40.5 \pm 0, 5$ g. Thereafter, the young male was observed a linear dynamic progression of weight: 252.01 g at 3 weeks; 829.46 g at the age of 8 weeks, 1293.5 g at the age of 12 weeks, respectively at 2240.5 g achieve sexual maturity (20 weeks). The best growth performance was noted in cockerels from farm 2 (total progress from hatching to adult stage of 2234.9 g).

In the case of pullets, the study presented a similar development, especially that, from 6 weeks of the life energy of growth was much lower than in cockerels, achieving, at the beginning of laying an average weight of 1604, 0 g, with limits 1577.8 ± 27.2 g (C4) and 1640.1 ± 29.3 g (C5).

Analyzing the data in tables 3.1. and 3.2., it is noted that the extent of aging of Leghorn breed, populations have become increasingly

nonhomogeneous regarding the development of body ($v = 15.8\% - 19.7\%$, to 20 weeks).

CONCLUSIONS

From the point of view of exterior features we can say that the studied specimens corresponded to standard breed successfully exteriorizing the specific characters of Mediterranean morpho-productive type but also the appropriate color varieties of which they belonged. However, it is desirable the introduction of new varieties of color in the studied populations.

Estimating the body weight, the following specifications can be made:

- development of body weight, in both sexes and age category of youth was within the breed specification, males reaching an average of 2.65 Kg GV at the age of 18 months and females 1.83 Kg G.V. at the same age.
